Part 1: The DAX query would be as follows to filter the 'Dataset' database and produce a table with all columns where the Card Type is "Platinum":

`FILTER('Dataset', 'Dataset'[Card Type] = "Platinum")` FilteredTable

In this query, 'Dataset' refers to the table that contains the data, while 'Card Type' refers to the column that contains the card types. The FILTER function filters the rows where the Card Type is "Platinum" and returns a new table called 'FilteredTable' with all of the columns from the original 'Dataset' database.

Part 2: `SUM('Table'[EstimatedSalary]) = SUM('Table'[EstimatedSalary])`
